

Main Mechanism in this FP

The Infix Meta Combination

When a term is applied to an argument,
the term and the argument are combined in a triple cell
and the first infix value in the term on this cell as a new argument
applied. You could also call it an infix combinator.

term is $(a_0\ i_0\ a_1\ i_1\ \dots\ \dots)$ *arg* is x

i_0 applied-on $((a_0\ i_0\ a_1\ i_1\ \dots\ \dots)\ _combine\ ..\ x)$

Essentially everything works in FP trivia according to this combinator mechanism.
In addition, the evaluator reacts to basic types [...] with its own interpretation ...
